Head-pose estimation

#### Head-pose classification

#### Our approach:

- Only estimate "yaw"
- Classification scheme.
- Discretize the range of yaw poses in steps of 15°.
- Estimate face orientation with a 13-class classifier.

→ Ξ → .

# Head-pose classification based on a Random Forest

- Ensemble of trees.
- Prediction determined by combining the outputs of all trees.
- For each tree, the leaf node provides a discrete distribution of head-pose.

Head-pose estimation

#### Image channels patches

Image channels. We extract 38 channels I<sup>α</sup>: gray-scale values, Sobel borders and 35 Gabor filters.

Head-pose estimation

#### Image channels patches

Image channels. We extract 38 channels I<sup>α</sup>: gray-scale values, Sobel borders and 35 Gabor filters.

■ Image patches. Randomly choose a set of square patches P<sub>i</sub> = {(I<sub>i</sub>, h<sub>i</sub>)}, where I<sub>i</sub> is the patch appearance and h<sub>i</sub> is the pose.

Head-pose estimation

Head-pose estimation

#### Patch-based channel features

• Our features  $\theta = (R_1, R_2, \alpha)$  are the difference between two rectangles,  $R_1$  and  $R_2$ , within the patch in channel  $\alpha$ .

$$f(oldsymbol{p}, heta) = rac{1}{|R_1|} \sum_{oldsymbol{q} \in R_1} \mathtt{I}^lpha(oldsymbol{q}) - rac{1}{|R_2|} \sum_{oldsymbol{q} \in R_2} \mathtt{I}^lpha(oldsymbol{q})$$

Head-pose estimation

・ 一 マ ト ・ 日 ト ・

Head-pose estimation

#### Training Regression Forest

- Train each decision tree using a randomly selected set of patches from a random subset of the training faces.
- Optimize each weak learner by selecting the  $\theta = (R_1, R_2, \alpha)$ , from a random pool of candidates  $\phi = (\theta, \tau)$ , that maximizes the information gain

$$IG(\phi) = \mathcal{H}(\mathcal{P}) - \sum_{S \in \{L,R\}} \frac{|\mathcal{P}_S(\phi)|}{|\mathcal{P}|} \mathcal{H}(\mathcal{P}_S(\phi)), \tag{1}$$

#### where

 $\tau$  is the threshold over the feature value,

$$\mathcal{P}_{L}(\phi) = \{\mathcal{P}|f(\mathcal{P},\theta) < \tau\},\ \mathcal{P}_{R}(\phi) = \mathcal{P} \setminus \mathcal{P}_{L}(\phi),\ \mathcal{H}(\mathcal{P}) = \log(\sigma\sqrt{2\pi e}).$$

Head-pose estimation

# Discrete pose estimation from face patches

# Pose estimation algorithm

- 1 Detect face bounding box in I.
- **2** Resize bounding box to  $W \times H$  pixels, denoted  $I_r$ .
- **3** Compute  $\alpha$  channels from  $I_r$ .
- 4 Extract from I<sub>r</sub> the set of input patches P of size N × N, with a stride of S pixels.
- **5** For each patch  $p_i \in \mathcal{P}$ :
  - **1** For each tree  $t_j$  in the forest:
    - **1** Input  $p_i$  to  $t_j$ .
    - 2 The leaf node of t<sub>j</sub> reached by p<sub>i</sub> provides a discrete distribution of the face orientation, p(yaw|p<sub>i</sub>, t<sub>j</sub>).
  - 2 Compute the patch face pose distribution,  $p(yaw|p_i) = \sum_j p(yaw|p_i, t_j).$

**6** Compute the final face pose distribution,  $p(yaw|I_r) = \sum_i p(yaw|p_i)$ .

< ロ > < 同 > < 回 > < 回 > .

# Algorithm configuration

- Resize face bounding box to  $105 \times 125$  pixels.
- Forest with T = 20 trees each trained on a random set of images equally distributed by yaw angle.
- Extract 20 random patches of  $61 \times 61$  pixels from face bounding box.
- Growing stops when depth reaches 15, or if there are less than 20 patches in a leaf.
- Select the best parameters from a pool of  $\phi = 50000$  samples obtained from  $\theta = 2000$  different combinations of [ $\alpha$ , R1, R2] and  $\tau = 25$  thresholds.
- The maximum random size of the subpatches defining the asymmetric areas R1 and R2 is set to be lower than a 75% of the patch size.

イロト イボト イヨト イヨト

Filter out leaves with a maximum variance threshold set to 400.

  - AFLW.
  - AFW.

Experiments

# Qualitative results

Results for *Pointing-04* (top), *AFLW* (middle) and *AFW* (bottom) databases.

Green and blue lines indicate respectively estimated pose and ground truth.

イロト イポト イヨト イヨト

Experiments

# Quantitative results in laboratory conditions

Our approach has a MAE close to the state-of-the-art.

Method	Pointing-04 MAE Accuracy (0°)		
Stiefelhagen ICPRW04	9.5°	52.0%	
Haj CVPR12	6.56°	67.36%	
Hara ECCV14	5.29°	-	
Geng CVPR14	4.24°	73.30%	
<b>Our method</b>	<b>7.84</b> °	55.19%	

All three approaches with best results use holistic HOG-based face features.

In this constrained context, a global feature is more informative for estimating face pose than the set of local patches.

- 4 同 ト 4 ヨ ト 4 ヨ ト

Experiments

# Quantivative results in real-world conditions

Our approach achieves the best performance.

Mathad	AFLW		AFW	
Method	MAE	Acc ( $\leq$ 15 $^{\circ}$ )	MAE	Acc ( $\leq$ 15 $^{\circ}$ )
Haj CVPR12	-	-	-	78.7%
Zhu CVPR12	-	-	-	81.0%
Sundararajan CVPR15	$17.48^{\circ}$	58.05%	17.20°	58.33%
Our method	<b>12.26</b> °	72.57%	<b>12.50</b> °	83.54%

Our approach can deal with challenging in-the-wild conditions, such as the presence of occlusions, illumination changes or facial expressions.

#### Conclusions

# Conclusions

We have presented an algorithm to estimate head-pose yaw angle in unconstrained settings

- Performs behind the state-of-the-art in laboratory conditions and better using "in the wild" databases.
- Local features provide good results in realistic imaging conditions.
- Achieves 80 FPS (12ms per image). It outperforms its competitors in terms of computational requirements.

Future use for estimation of facial attributes.

- 4 同 ト 4 ヨ ト 4 ヨ ト
